Volunteers Needed for a Novel Study to
Restore Standing and Walking In Paralyzed Individuals

Spinal cord injury (SCI) affects over 250,000 people in the United States with 12,000 new cases occurring each year. It is a devastating injury resulting in either temporary or permanent loss of ability to move or feel the arms and legs, loss of ability to control bowel and bladder function, and paralysis in general. Animal research in the past 15 years by scientists and engineers (Dr. Mushahwar and others) have shown that it is possible in animals to restore standing or walking through precise control of hair-like, micro-wires into the spinal cord. We believe that such exciting technology can be offered to humans with similar types of injury.

The Department of Defense has sponsored a clinical trial in order to determine whether this technology is even feasible in humans. We are asking individuals with complete spinal cord injury (T2-T8 level) who are planning to undergo a thoracic spine surgery to allow us to map the lower spinal cord with microelectrodes to prove this concept. Our strategy offers a novel, ground breaking study that will likely lead to a new generation of medical devices to restore standing and gait in SCI individuals. We are particularly interested in rehabilitation solutions for SCI individuals that have been injured in OIF/OEF campaigns.

To see if you are eligible, please view enrollment and study details at www.XXXXX.com or call ISMS Study Coordinator – Melba Isom, 615-875-5853

Travel compensation is available and will be discussed at the time of your call to the study coordinator.
